SILICON COMPOSERS INC

FAST Forth Native-Language Embedded Computers

Harris RTX 2000tm 16-bit Forth Chip

- 8 or 10 MHz operation and 15 MIPS speed.
- 1-cycle $16 \times 16 = 32$ -bit multiply.
- 1-cycle 14-prioritized interrupts.
- two 256-word stack memories.
- 8-channel I/O bus & 3 timer/counters.

SC/FOX PCS (Parallel Coprocessor System)

- RTX 2000 industrial PGA CPU; 8 & 10 MHz.
- System speed options: 8 or 10 MHz.
- 32 KB to 1 MB 0-wait-state static RAM.
- Full-length PC/XT/AT plug-in (6-layer) board.

SC/FOX VME SBC (Single Board Computer)

- RTX 2000 industrial PGA CPU; 8, 10, 12 MHz.
- Bus Master, System Controller, or Bus Slave.
- Up to 640 KB 0-wait-state static RAM.
- 233mm x 160mm 6U size (6-layer) board.

SC/FOX CUB (Single Board Computer)

- RTX 2000 PLCC or 2001A PLCC chip.
- System speed options: 8, 10, or 12 MHz.
- 32 KB to 256 KB 0-wait-state SRAM.
- 100mm by 100mm size (4-layer) board.

SC32tm 32-bit Forth Microprocessor

- 8 or 10 MHz operation and 15 MIPS speed.
- 1-clock cycle instruction execution.
- Contiguous 16 GB data and 2 GB code space.
- Stack depths limited only by available memory.
- Bus request/bus grant lines with on-chip tristate.

SC/FOX SBC32 (Single Board Computer32)

- 32-bit SC32 industrial grade Forth PGA CPU.
- System speed options: 8 or 10 MHz.
- 32 KB to 512 KB 0-wait-state static RAM.
- 100mm by 160mm Eurocard size (4-layer) board.

SC/FOX PCS32 (Parallel Coprocessor System32)

- 32-bit SC32 industrial grade Forth PGA CPU.
- System speed options: 8 or 10 MHz.
- 64 KB to 1 MB 0-wait-state static RAM.
- Full-length PC/XT/AT plug-in (6-layer) board.

SC/FOX SBC (Single Board Computer)

- RTX 2000 industrial grade PGA CPU.
- System speed options: 8, 10, or 12 MHz.
- 32 KB to 512 KB 0-wait-state static RAM.
- 100mm by 160mm Eurocard size (4-layer) board.

Features

9 Universal Control Structures *Kevin Haddock*

Forth's execution control can be difficult to learn, and control structures can be an area of concern even for the enlightened. Forth has all the advantages of an interpreted language like BASIC but, again, the control structures get in the way.

One thing that creates difficulty with Forth, compared to C, is eliminating unnecessary tests: If any one of a series of ANDed conditions is not true, there is no need to waste time extracting and evaluating subsequent conditions. This article attempts to provide an integrated solution that is uniform, clean, simple, and Forth-like.

17 Neural Network Words *Tim Hendtlass*

Neural networks are good at certain tasks the human brain is good at, like pattern recognition, often outperforming traditional computing techniques. A neural network is an interconnection of special processing elements that is based on the brain; each element has inputs and outputs, and is termed a "neurone." Neurones are arranged in logical layers, and a collection of such layers comprises a network.

The code in this article allows construction of a class of simulated networks, and their training by the widely used technique called "back propagation." It is portable to many environments, and other training techniques may be incorporated. (The second of two articles.)

24 Ada Multiprocessor Real-Time Kernel *Hoyt A. Stearns, Jr.*

A fully pre-emptive, priority driven, multiprocessing real-time kernel is required in certain applications, and the Ada rendezvous method is simple, straightforward, and elegant. Ada multitasking will work on multiple processors or on a single processor. A task can be local to a particular processor, or can be distributed.

The listing is the kernel for a system with three processors, but the kernel works fine on a single-processor system.

Editorial

A last reminder: *FD* has announced a call for papers about object-oriented programming. The closing date is September 16 for prize consideration—see our ad on page 37 for prize information, and refer to the editorial in issue XIII/1 for other details that may be helpful when preparing your paper. (Papers received after the deadline will still be evaluated for publication.)

So, Why Don't You Write?

FD is also looking for many new articles from its readers to fill the editorial coffers. This is, after all, a reader-written publication—this means you! We are looking for a wide range of topics, as eclectic as our readership. Chances are, if you find something interesting, clever, or challenging, many others will, too. If you aren't sure, just drop me a note that outlines the idea, and I will try to give meaningful feedback to you. (And check out our "Author Recognition Program," details of which are reprinted on page 35.)

If you aren't sure if your idea is really a new one, or can't remember whose original work it derives from—to say nothing of the times when you wonder whether the blank wall you've been staring at has been scaled

already by some other Forth explorer—there are some FIG reference tools you might want to get. Look on the FIG Mail Order Form for the "We're Sure You Wanted to Know..." series. The Forth Bibliography from Rochester also provides Forth reference information from outside the FIG domain, but hasn't been updated since January 1987. Get a copy anyway for an inspirational look at how much Forth material really has been circulating through the years.

Chinese National Exam of Forth Programmers

China has officially announced a national examination to be held in September. Great importance is often attached to the results of such examinations. As Dr. Ting relates, the Chinese love examinations, a tradition of 2000 years. For your interest, following is a translation of part of the announcement:

To accelerate the application of Forth in various technical fields, to enlarge the ranks of Forth programmers, to raise the expertise in the Forth language, and to satisfy the increasing need for Forth users, the Chinese Scientific Instrumentation Society, the Chinese Software Association, and the Chinese Forth Interest Group will

jointly sponsor a National Examination of Forth Programmers on September 8, 1991 in various provinces and cities across China. The sponsors will grant certificates to programmers passing this examination. They will also select the best ten Forth programmers and thirty excellent Forth programmers, based on the examination, to receive special certificates and awards, to be recommended to participate in Forth projects, and to carry out advanced studies abroad.

Subjects of Examination

1. Computer Fundamentals (20%)
 - Number systems and conversions
 - Internal representations of numbers
 - Major components in a computer and their relationships
 - Instructions and instruction sets
 - Characteristics and functions of registers
 - Characteristics and properties of I/O devices
 - Data structures (stacks and lists)
 - Operating system fundamentals
 - Software engineering fundamentals
2. Elementary Knowledge of

The Forth Interest Group

The Forth Interest Group is the association of programmers, managers, and engineers who create practical, Forth-based solutions to real-world needs. Many research hardware and software designs that will advance the general state of the art. FIG provides a climate of intellectual exchange and benefits intended to assist each of its members. Publications, conferences, seminars, telecommunications, and area chapter meetings are among its activities.

"*Forth Dimensions* (ISSN 0884-0822) is published bimonthly for \$40/46/52 per year by the Forth Interest Group, 1330 S. Bascom Ave., Suite D, San Jose, CA 95128. Second-class postage paid at San Jose, CA. POSTMASTER: Send address changes to *Forth Dimensions*, P.O. Box 8231, San Jose, CA 95155."

Letters

Letters to the Editor—and to your fellow readers—are always welcome. Respond to articles, describe your latest projects, ask for input, advise the Forth community, or simply share a recent insight. Code is also welcome, but is optional. Letters may be edited for clarity and length. We want to hear from you!

Black-Belt Exhaustion & Lean, Mean FIG

Dear Phil Koopman, Jr.:

I was sorry to hear that you decided to drop your FIG membership [see *FD* XIII/2]. You are one of the very visible and highly acclaimed Forth programmers. It is a great loss to FIG, not having you continue your membership.

You correctly pointed out that FIG is having financial troubles. The main problem I see is that we have been losing members since 1984, when the membership peaked at about 4,500. The current membership of about 2000 cannot support the operation of FIG using a professional support organization like ADC.

The membership loss has puzzled me all these years. There are more computers, more users, but why is FIG getting leaner and leaner? We have tried many different things to attract more new members, as well as to keep the old ones, but nothing seemed to work. There were substantial improvements on the appearance and substance in *FD*. We put lots of effort into getting the GENie Forth RoundTable

going. We had gone out of our way to promote Forth to the outside, but to no avail. Harris put in great amounts of money and energy to promote Forth, and even assembled a very high-powered team of Forth black-belts, including yourself, to develop the turbo-charged Forth engines. Why did Harris abandon its efforts? I really hope that somebody will tell me what's going on and what we have to do to change the public perception of the inadequacies of Forth and FIG.

FIG has always been an organization of volunteers. The founders of FIG expended great energy to craft fig-Forth, which propelled FIG into a viable association. Other members like Mike Perry, Henry Laxen, Bob Smith, and Tom Zimmer improved on fig-Forth and contributed F83 and F-PC, which have kept FIG going. I am fully aware of your contributions to Forth, in MVP-FORTH and the WISC technology. However, may I ask what you have contributed to FIG as a member? You complained that there is not a FIG chapter in your area. Every chapter is started

by somebody; have you considered starting one yourself? You certainly have the capability, the energy, and the charisma to lead a large group and to teach lots of newcomers. Maybe the reason that FIG is shrinking is due to the exhaustion of leaders like you?

I had not served on the FIG Board of Directors until last year. However, I have regularly attended the business meetings and watched FIG's operations for ten years. One thing I can say for the Board is that every dollar is accounted for and the records are kept accurately. All expenses are openly discussed and must be approved at these meetings. The books are available at the FIG office for members to inspect. *Forth Dimensions* will also be publishing financial reports. [See the President's Letter in this issue. —Ed.]

I appreciate that you took the trouble to write and tell us what you think of FIG. I fully understand your frustration, and respect your

countryside. He asked the old man why he was crying. The old man said, "I presented this piece of rock to your grandfather because it contains a large jade. Your grandfather let his jade expert inspect it, and he said, 'It's just a stone.' So, your grandfather cut off my right leg. Then I presented it to your father. Your father had it inspected, and he cut off my left leg. I cannot walk any more. Then Heaven brought you here so I can see you. Here is the rock. It's yours, if you can use it." The King of Tsu ordered his jade worker to saw it open and found the largest and the most beautiful jade ever seen in China. It was from this jade that the First Emperor of China made his imperial seal.

Forth is like this piece of jade in a rock. We know it is the best tool for human beings to control computers. We tried to give it to the world, but what did we get back? Both feet cut off. What can we do? I think all we can do is stick together, keep warm, and keep the pot

There's no reason why metacompilers should be hard to learn, use, or understand...

decision not to continue your membership. However, I think the greatest challenge we Forth programmers all face is not just to survive the onslaught of C and Unix, but to pool our resources together and find the niche where Forth can still grow and shine.

Let me repeat an ancient Chinese story to make my point. The King of Tsu met an old man, crying in the

stirred. If Forth is really that good, it will shine eventually. When? I do not think anybody knows. FIG is the only place where we can keep ourselves warm.

Dr. C.H. Ting
San Mateo, California

Mastering Metacompilation

Dear Editor,

Metacompilation is get-

ting a bum rap.

Recent postings on GEnie, and an item by Dr. C.H. Ting in *Forth Dimensions* ("How Metacompilation Stops the Growth Rate of Forth Programmers," *FDXIII/1*), have re-opened one of the dark closets of Forth: metacompilation.

Metacompilation is probably the most arcane aspect of Forth, and is usually considered the province of the Forth "priesthood." I sympathize. But I think it's a mistake to abandon metacompilation for assembly language source, as Dr. Ting advocates. This is like going back to gas lighting because people get shocked by (and don't understand) electricity.

Education is the answer.

For the last four years, I've been saying that the problem is *not* that there aren't good Forth metacompilers, but that there isn't any good *documentation* for metacompilers.

I've come up through this the hard way. My first experience with a metacompiler (cross-compiler) was in 1982, when I tried to use a commercial product. The documentation was incomprehensible, the compiler obscure. Finally, I was able to complete my project by hacking my code onto the kernel supplied with the compiler, and by abandoning any attempt to use defining words, IMMEDIATE words, or vocabularies. (Rather like programming in C, come to think of it.)

My second experience was with a version of Cassady's Metaforth, implemented and modified by a friend of mine. I began to

Figure One. The probability of matching birthdays.

BIGSIZEMAX size (an even number of bytes) of biggest number needed.

BIG area of memory which holds a multiple-length unsigned number, two bytes longer than BIGSIZEMAX since the most significant cell is used to monitor overflow.

BIGLOW address of least significant cell of BIG number.

BIG! (u --) sets BIG number to u.

BIG@ (-- u) fetches u from least significant cell of BIG number.

BIGSIZE (-- u) returns the size (rounded up to an even number of bytes) of BIG number, excluding leading zeroes.

BIG* (u --) multiplies BIG number by u; product is new BIG number.

BIG/MOD (u1 -- u2) divides BIG number by u1; quotient is new BIG number, remainder is u2.

PEOPLE (n --) calculates and displays the probability of at least one pair of matching birthdays in a group of n people.

```

understand the workings of the compiler, but even with my friend as a resource, I couldn't decipher how to add defining words or vocabularies.

The breakthrough came on my third attempt: the polyFORTH target compiler. And the reason for the breakthrough is not that the compiler is that much simpler (although it's certainly elegant!), but that I was able to attend the polyFORTH ad-

vanced course and have someone *teach* me how metacompilers work. Enlightenment!

I then proceeded to test my understanding of the theory and practice of metacompilers, by writing one of my own. (I had other reasons for this—I needed features that no one else was offering.) But, remembering how much difficulty I had in acquiring the essential concepts, I resolved to keep notes and record my thoughts *as I wrote the compiler*. I think

I may be the first person to document the process of discovery this way.

In December of 1988 I condensed these notes into a one-hour presentation for our local FIG chapter, and was amply rewarded. Even though I delivered it at warp speed, several people came up to me afterward and told me that they understood metacompilation for the first time.

The lesson I learned from giving this talk is this: there's

no reason why metacompilers should be hard to learn, use, or understand. The concepts aren't complicated; it's just that everyone who understands metacompilers takes them for granted!

Frank Sergeant, in *Forth Dimensions* XII/6, has started to dispel the mystery of metacompilation, by presenting a clear description of an elegant compiler. Like eForth, Pygmy is being ported to many CPUs in the embed-

HARVARD SOFTWARES

NUMBER ONE IN FORTH INNOVATION

(513) 748-0390 P.O. Box 69, Springboro, OH 45066

MEET THAT DEADLINE !!!

- Use subroutine libraries written for other languages! More efficiently!
- Combine raw power of extensible languages with convenience of carefully implemented functions!
- Yes, it is faster than optimized C!
- Compile 40,000 lines per minute!
- Stay totally interactive, even while compiling!
- Program at any level of abstraction from machine code thru application specific language with equal ease and efficiency!
- Alter routines without recompiling!
- Use source code for 2500 functions!
- Use data structures, control structures, and interface protocols from any other language!
- Implement borrowed feature, often more efficiently than in the source!
- Use an architecture that supports small programs or full megabyte ones with a single version!
- Forget chaotic syntax requirements!
- Outperform good programmers stuck using conventional languages! (But only until they also switch.)

HS/FORTH with FOOPS - The only full multiple inheritance interactive object oriented language under MSDOS!

Seeing is believing, OOL's really are incredible at simplifying important parts of any significant program. So naturally the theoreticians drive the idea into the ground trying to bend all tasks to their noble mold. Add on OOL's provide a better solution, but only Forth allows the add on to blend in as an integral part of the language and only HS/FORTH provides true multiple inheritance & membership.

Lets define classes BODY, ARM, and ROBOT, with methods MOVE and RAISE. The ROBOT class inherits:

```
INHERIT> BODY
HAS> ARM RightArm
HAS> ARM LeftArm
```

If Simon, Alvin, and Theodore are robots we could control them with:
Alvin's RightArm RAISE or:
+5 -10 Simon MOVE or:
+5 +20 FOR-ALL ROBOT MOVE
Now that is a null learning curve!

WAKE UP !!!

Forth is no longer a language that tempts programmers with "great expectations", then frustrates them with the need to reinvent simple tools expected in any commercial language.

HS/FORTH Meets Your Needs!

Don't judge Forth by public domain products or ones from vendors primarily interested in consulting - they profit from not providing needed tools! Public domain versions are cheap - if your time is worthless. Useful in learning Forth's basics, they fail to show its true potential. Not to mention being s-l-o-w.

We don't shortchange you with promises. We provide implemented functions to help you complete your application quickly. And we ask you not to shortchange us by trying to save a few bucks using inadequate public domain or pirate versions. We worked hard coming up with the ideas that you now see sprouting up in other Forths. We won't throw in the towel, but the drain on resources delays the introduction of even better tools. Don't kid yourself, you are not just another drop in the bucket, your personal decision really does matter. In return, we'll provide you with the best tools money can buy.

The only limit with Forth is your own imagination!

You can't add extensibility to fossilized compilers. You are at the mercy of that language's vendor. You can easily add features from other languages to HS/FORTH. And using our automatic optimizer or learning a very little bit of assembly language makes your addition zip along as well as in the parent language.

Speaking of assembly language, learning it in a supportive Forth environment turns the learning curve into a light speed escalator. People who failed previous attempts to use assembly language, conquer it in a few hours or days using HS/FORTH.

HS/FORTH runs under MSDOS or PCDOS, or from ROM. Each level includes all features of lower ones. Level upgrades: \$25. plus price difference between levels. Source code is in ordinary ASCII text files.

All HS/FORTH systems support full megabyte or larger programs & data, and run faster than any 64k limited ones even without automatic optimization -- which accepts almost anything and accelerates to near assembly language speed. Optimizer, assembler, and tools can load transiently. Resize segments, redefine words, eliminate headers without recompiling. Compile 79 and 83 Standard plus F83 programs.

PERSONAL LEVEL \$299.
NEW! Fast direct to video memory text & scaled/clipped/windowed graphics in bit blit windows, mono, cga, ega, vga, all ellipsoids, splines, bezier curves, arcs, turtles; lightning fast pattern drawing even with irregular boundaries; powerful parsing, formatting, file and device I/O; DOS shells; interrupt handlers; call high level Forth from interrupts; single step trace, decompiler; music; compile 40,000 lines per minute, stacks; file search paths; format to strings. software floating point, trig, transcendental, 18 digit integer & scaled integer math; vars: A B * IS C compiles to 4 words, 1.4 dimension var arrays; automatic optimizer for machine code speed.

PROFESSIONAL LEVEL \$399.
hardware floating point - data structures for all data types from simple thru complex 4D var arrays - operations complete thru complex hyperbolics; turnkey, seal; interactive dynamic linker for foreign subroutine libraries; round robin & interrupt driven multitaskers; dynamic string manager; file blocks, sector mapped blocks; x86&7 assemblers.

PRODUCTION LEVEL \$499.
Metacompiler: DOS/ROM/direct/indirect; threaded systems start at 200 bytes, Forth cores from 2 kbytes; C data structures & struct+ compiler; TurboWindow-C MetaGraphics library, 200 graphic/window functions, PostScript style line attributes & fonts, viewports.
ONLINE GLOSSARY \$ 45.

PROFESSIONAL and PRODUCTION LEVEL EXTENSIONS:

FOOPS+ with multiple inheritance \$ 79.
TOOLS & TOYS DISK \$ 79.
286FORTH or 386FORTH \$299.

16 Megabyte physical address space or gigabyte virtual for programs and data; DOS & BIOS fully and freely available; 32 bit address/operand range with 386.
ROMULUS HS/FORTH from ROM \$ 99.
FFORTRAN translator/mathpak \$ 79.
Compile Fortran subroutines! Formulas, logic, do loops, arrays; matrix math, FFT, linear equations, random numbers.

Shipping/system: US: \$7. Canada: \$19. foreign: \$49. We accept MC, VISA, & AmEx

Universal Control Structures

Kevin Haddock
Chico, California

When I first started working with Forth, it's execution control was one of the most difficult aspects to learn. The basic words weren't difficult to understand—but I was encountering frustration trying to make my programs fit into the mold those words wanted to impose on them.

After seeing the wisdom of everything else Forth has to offer—simplicity, factoring, bottom-up design, performance, and economy, to name a few—I see evidence that control structures are an area of concern even for the enlightened few.

Indications of this can be found in the numerous efforts at case statements: Parnas' IT ... TI (FD VI/1), and security-less (e.g., poly-) Forth's gymnastic mixing and matching of incompatible types of control operators by bouncing offset addresses around on the stack at compile time.

I have always claimed that Forth has all the advantages of an interpreted language like BASIC, but here again the control structures get in the way. In BASIC, you can always whip up a quick loop or check the logic of your code with a conditional typed at the command line.

I have seen this interpre-

tative situation addressed to some degree, but to date I have not seen an integrated solution that is uniform, clean, simple, and "Forth-like." (If I can judge what is "Forth-like"; the debate rages on!).

I was discussing the situation with a Forth-wiser friend of mine when I made the first step in stumbling upon the solution. Sometimes the hardest solution to see is the one that is right in front of your nose. (This happens a lot with me, especially when it comes to Forth.)

He said, "You know, Kevin, there really are only two control operators in

Forth, in comparison with C, for example, was crafting the code to eliminate unnecessary tests. If any one of a series of ANDed conditions is not true, there is no need to waste any more time extracting and evaluating subsequent conditions. Similarly, if any one in a series of ORed conditions is true, processing can continue in the body of the condition. Since real-time is one of Forth's strengths, how come it falls so flat in this area? Control structures!

While writing my on-line classified ad system in Bourne Shell, I recall having fun

Since real-time is one of Forth's strengths, how come it falls so flat in this area? Control structures!

Forth, BRANCH and 0BRANCH (and ?BRANCH in the newer versions). You can do whatever you want with those." Well, I knew that on an intellectual level, but this forced me to focus, it got my wheels turning. I know the wheels of my mind grind exceedingly slow, but I would like to think they grind exceedingly fine!

One of the things that created the most difficulty working with traditional

seeing how many of my conditional needs could be met with the || (OR) and && (AND) operators, which would drop out of the current line of script if the previous command returned true or false, respectively. I was pleasantly surprised at how comfortable it was working with this arrangement, although it required a slightly different mode of thought than is conventionally used in programming. I could appease

my old modes of thought by coining the pet names: `ifso` for `&` and `ifnot` for `|`. (Since there was little collision with Forth words, I opted for the single-character versions.) You can use whatever emotional crutch feels the most appropriate to you, or none at all.

It was apparent that just falling out of the line (or colon definition) was inadequate for my needs. Most people aren't willing to factor their definitions to that level, nor should they have to. There was also the question of looping, restarting the execution at some previous point in the code.

Those operators `&` and `|` marked a point of departure, but there needed to be something (other than `:` and `;`) to mark the points of return. In other words, if `&` and `|` caused you to break out of the execution of the code, based on some condition, where do you land? Other languages have their `endifs`, `thens`, `line terminators`, etc. After serious deliberation, I decided to confiscate C's block delimiters `{` and `}`.

I know, I hear you saying, "Here is just another character trying to make Forth more C-like," but trust me, the icons are where the similarity ends. Years ago, someone suggested they look like profiles of faces, and I took it one step further by saying that, together, they resembled the faces, comedy and tragedy, of live theater.

With this worked out, conditionals `|` and `&` from which to branch, and layers of balanced control block delimiters, I had discovered how to lay down the `0BRANCH` control ops. The only thing left to determine was how to lay down the

Figure One. UCS primitives.

Icon	Say	Description
{	comedy	Begins a new control block.
}	tragedy	Ends the most recently open block.
(Note: these can nest to any depth)		
&	ifso	Falls or "sinks" out of the current control block if the top of stack is false.
	ifnot	Same as above if TOS is true.
^	float 1	Rises back to the top of the current control block.
^^	float 2	Rises back to the beginning of the control block before this one.
^^^ ^^^^ ...		Logical extension of the above.
v	sink 1	Falls through or "sinks" to the end of the current control block.
vv	sink 2	Falls through or "sinks" to the end of the second subsequent control block.
vvv vvvv ...		Logical extension of the above.

BRANCH ops responsible for looping and skipping the ELSE part of a conditional construct.

My solution was to use combinations of one or more carets (^) and lower-case v's (you can use upper case, if your system converts case automatically) to specify that execution was to float or sink that many control block levels. (Actually, "levels" is probably the wrong word here. You are actually "de-nesting" if you are thinking in terms of C, but what matters is whether you de-nest toward the top or the bottom of the program.)

Let me see if I can bring this all together for you in Figure One. You will notice later that sink 1 (v) is never needed: the default behavior is to fall out of the current block at the end. `&` and `|` serve the purpose of falling

out of the current block before the end, based on a condition.

Some of you may find that a caret (^) is difficult to enter with your editor, especially if yours is patterned after the Forth, Inc. line editor, which uses it as a delimiter. Two alternatives exist. Presented in the order of my personal preference:

- Change your editor's delimiter to something else; my suggestion would be a line feed; this character shouldn't have too adverse

an affect on any video updating and, since it's non-printable, you would be highly unlikely to want to enter it into your source code.

Or:

- Change the icon used for the float (^). You could use the tilde (~), which on most CRT's looks like a bubble, and that could be your memory aid: The more bubbles, the higher it will float.

Another thing you will

Kevin Haddock's first Forth—a FIG model adapted from CP/M—came from an OASIS users group. After switching himself and his customers over to MS-DOS and Unix, he worked in a network access control system done in native polyFORTH, a spinoff of the King Khalid Airport in Saudi Arabia. On the side, he cannibalized some Commodore 64s and built a native fig-FORTH system on the C-64's motherboard, using a small daughterboard; this provided SCSI, RS-232, and Centronix capabilities almost entirely in software. Lately he has been finishing up a Forth written in C, not feeling that previous efforts to do this really captured the essence of Forth. He says, "Usually the inner interpreters were unconventional (e.g., case statements, jump tables, etc.) and provided little portability or comfort to Forthers seeking familiarity in an alien (e.g., Unix) environment."

UCS — F83 version.

notice is that the branch operators (^ and v) and their derivatives (^, ^^, vv, vvv, etc.) will always appear just before tragedy(). There may be some elegant way of combining the two, but I haven't found any. Also, since comedy and tragedy don't really take up any compiled memory, there is no real loss.

Some may argue that the universal control structures (UCS) are nothing more than an elaborate GOTO scheme. Albeit that some may use this tool to take Forth further down the path of obfuscation by creating even more poorly factored and deeply nested eyesores, I must defend the utility by saying that with the requirement to keep the control delimiters balanced, you would have a very difficult time branching wildly into the center of some block of code without clearly indicating your intentions.

I hope this utility will be a win-win situation for all users. The vertical-obfuscated-code people will be able to nest deeper than ever before (if that can be considered a win); the horizontal factorers can construct the structure to exactly what they want; and the poly-, cm-, and Pygmy-Forth types can get even wilder than before (this utility is great for passing control out of one word and into the middle of another, for example).

As you will see, there are actually two versions of each word, one for executing and another for interpreting. These are combined into one state-smart word where applicable; this may be one of the few places where a state-smart word may be excusable, since there is only a slight compile-time penalty and no run-time penalty.

A note of caution is in

(Continues.)

order here: the interpreted version just does a string search for the balancing control delimiter, so remember: if you use braces—er, faces—in your words or in comments, always use them in balance. For instance, you could name a word {FRED} but try to avoid {FRED unless it is to be followed almost immediately with something like FRED}. This is the only minor un-Forth-like limitation on syntax, but I feel it is a small price to pay for the benefit received.

Possible uses for the interpreted version could be compilation scripts, non-time-critical routines, memory-critical programs, debugging with zero compile time, and my favorite: a late-binding, object-oriented system where methods could exist in different vocabularies that know how to deal with their own data types. You select the context by determining what kind of data object you are dealing with, then process the actual, reusable algorithm interpretatively from disk. With the old FIG-style hierarchical vocabularies, you could essentially build superclasses.

And now for the moment you have all been waiting for: on to the code!

Due to the drastically different behavior of the compiled and interpreted operators, I will describe them separately, even though some versions of Forth will bundle them into the same state-smart word.

It goes without saying that all control structures are compiler directives and, therefore, have precedence in whatever mechanism is appropriate for your Forth.

While compiling, UCS holds a pair of addresses on the stack for each open con-

```
>NEXT -- adjusts the input stream pointer based on the
      sign of the given number

I~ -- adjusts the interpretative pointer to the given control
     block. Negative control block offsets move the adjust the
     pointer forward. Positive or zero backward.

I&| -- adjust the interpretative pointer to the end of the
      current control block.

{ -- denotes the start of a control block.

& -- falls out of the current control block if given value is
     false

| -- falls out of the current control block if given value is
     true

} -- marks the end of a control block. When compiling, this
     word resolves all the forward references for this block.
```

trol block. The top one points to a null-terminated thread of forward branch offset cells (the ones compiled right after the BRANCH and OBRANCH ops) for the current control block. The second one holds the address of the beginning of the control block, to resolve the backward branches.

Comedy ({} just leaves the current dictionary address and the initial 0 on the stack.

Ifso (&) compiles the conditional branch op OBRANCH, pushes the address of the offset cell following it (HERE), then compiles (comma's) the previous (possibly null) forward reference link there. This adds the next link in the forward reference chain.

Ifnot (!) is self-explanatory, just compiling an op to invert the test for ifso.

All the floaters and sinkers are just user interfaces to a word that digs down in the compile-time stack, either to link into the appropriate forward thread or to resolve a backward branch.

Tragedy (|) just tosses the control block start address left by comedy, then loops through the thread, resolving the forward branches until terminated by the null link.

The interpreted versions of comedy and tragedy do nothing except act as targets for character scanning.

In an actual installation, the character-scanning primitives (consisting of the words @CHAR, ACCOUNT, >NEXT, and \~, and even the loops in & and |) should be in machine code. I will leave it as an exercise to you, the reader, to work this out. Suffice it to say the code just scans the input stream pointer across the text until it finds the appropriate level of imbalanced open or closed braces. Also, you will note in

(Continues.)

the Pygmy version, this gives us our first live example of compiled UCS in action. I also leave it as an exercise to re-code the compilable part of UCS for metacompiling (and even your Forth nucleus, if you get so inspired). I'm not saying a Forth should not have the traditional control structures, just that it might be a more elegant solution defining them and Forth in terms of UCS, rather than the other way around.

Included in the listings are some quick examples: a case statement in the form of what could be a key/command loop, both in interpreted and compiled form; a memory dump utility; and a simple utility to create memory headers that will go out and interpretively load blocks, saving memory and compilation time (also with possible object-oriented implications as mentioned earlier).

As a final note, remember to keep an eye on your stack depth changes before and after compiling. The UCS have, and need, no compiler security. Too many comedies will grow your stack and too many tragedies will shrink it. Minimalists should already be familiar with this technique.

I hope you will have as much fun playing with, and improving upon, the UCS as I did discovering them. Enjoy!

Forth on the Macintosh

Laughing Water of Helena, Montana, told us about his becoming a Forth defector on the Macintosh in the May/June issue of *Forth Dimensions*. It is, in many ways, his article that incites the writing of this one.

I have used Forth on the Macintosh since the early days of the 128K Mac. I have had a running application going and in daily use—developed in Mac4Th at first and later finalized in MACH2 Forth—for about five years now. It controls a studio 1/4" tape recorder, greatly facilitating the logging and locating of sound effects, atmospheres and daily dialogue takes in my work as film sound recorder and dubbing editor. But I, too, have during the last year or so become somewhat of a Forth defector, using more and more time with other Macintosh developing environments, MPW to be more precise. Note I use the word environment and not language.

A quote from Laughing Water: "Besides, the Mac listens better when I talk Pascal." I read: "The Pascal environment he uses is better than the Forth one, or at least better understood."

With today's Mac programming choices—MPW

(Pascal, C, C++, MacApp, Assembler), MDS Assembler, Language Systems Fortran, MacFortran, Prograph, Smalltalk, Think C, TLM Pascal, True Basic, Lisp, Modula2, Simula, MacForth (still on sale), Mach2 Forth (no more advertised), Neon (become public domain), MasterForth (not supported for a long time), Pocket Forth, Hypercard, and... as well as the many dBase-like languages like Omnis, 4th Dimension, etc.—sure the Mac “speaks many languages,” but the environments are “oh, so different.”

Macintosh programmers are busy generating standalone applications and adhering rigidly to Apple's programming guidelines. Forth is not concerned with that. (How could it be?)

The majority of Forth code exchanged within the Forth community in journals like *Forth Dimensions* and the *Journal of Forth Application and Research* doesn't deal with standalone applications,

Forth community lost its last meeting platform. Whatever happened to the MacForth user group? The last newsletter I got was sometime in late 1986!

The Forth community is, naturally, busy debating Forth. And it is mostly machine independent.

The Forth compiler and interpreter is a powerful tool, in itself, that is always present. This is perhaps the major and most important difference between Forth and any other language, and is immensely hard to explain to non-Forthers. A lot of Forth's power lies precisely in its accessibility: the ability to extend the compiler and interpreter, to add to it, to use or abuse it (refer to Defector's reference to anarchy) within new definitions. The fact is that the processor is there for you to use, directly from an interactive console or via some prior compilation.

On the Mac, we are expected to program so that, ultimately, the Forth layer

There is no reason why the vast programming utilities of MPW could not become available to the Forth environment.

and only a very few times do they approach the subject of a Mac-like graphical user interface. Never, I believe, have they dealt with Macintosh issues in particular.

The Macintosh community is, naturally, debating Macintosh issues with all its virtues and quirks. When *Mactutor's* Forth column was stopped in favor of C++ and MacApp, the Macintosh's

will not be present. No more definable words, no more vocabularies, no more Forth interpreter! Some of Apple's programming guidelines also affect the available Forths directly. For example: not to use any of the 68000 trap mechanisms, and not to use in-line variables in code segments (due to future instruction caching). Words like

Neural Network Words

Tim Hendtlass

Hawthorn, Victoria, Australia

THE LAST OF TWO PARTS

In part one of "Neural Network Words," a number of words were developed to build and train neural networks. Words are now presented to save a network layer to disk. Most networks will learn from real life data rather than from an artificial example, such as the XOR relationship used in part one. The advantages of scaling the real life input and output values to suitable internal values for the neurones used was also demonstrated in part one.

Working out scaling factors is tedious, at best, and words are now presented to

layer to disk. The address of the layer to save must be on the stack on entry, and the name of the file to create must immediately follow SAVE-LAYER on the current input line. If a file by this name already exists, the user is asked for permission to overwrite it.

READ-LAYER

This word restores a neural layer from disk. The layer must have been created before the word is called. The address of the layer to copy to must be on the stack on entry, and the name of the file to read must immediately follow READ-LAYER on the current input line. No check is made to see that the layer being read to has the same dimensions as the layer on disk.

Words to read a data file

Data files used by this software are simple ASCII files, with one set of input values and one set of output values per line. No explicit provision is made in this version for comments, although anything on a line after the specified number of inputs and outputs will be skipped over. The variable N-IN

specifies the number of inputs to the whole network, the variable N-OUT the number of outputs from the whole network. READ# reads one number from the current input and scales it into internal form.

The convenient word PROCESS-FILE saves information about what we were doing and moves up one handle on the handle stack. It then opens a new file, processes it, closes it, and returns to what we were doing when the PROCESS-FILE word was encountered. PROCESS-FILE must be followed directly by the name of the file to use, and processing continues immediately after the filename. The actual processing done is controlled by the deferred word (PROCESS-FILE) which can be set to anything at all. SET-SCALES and TEACH-NETWORK (see below) differ mainly in what (PROCESS-FILE) is equated to.

Scaling words

SET-SCALES reads the file specified immediately following this word. It finds the maximum and minimum input and output numbers,

The more complicated the relationship to be learned, the more neurones will be needed.

ERRATA

In the first part of this article (FD XIII/2), we erroneously printed an incorrect figure. In that issue, the Forth file printed as Figure Eight (beginning on page 20) actually contains words related to disk I/O, which is discussed in this installment. Please refer to it for that code. In turn, the file NNDEMO.SEQ, which should have been printed last time as Figure Eight, appears herewith. We apologize to the author and to any readers who were inconvenienced.

The author also wishes to note that in DISKNN.SEQ (the file which appeared last time as Figure Eight), he used a couple of outdated word names in the opening comment: NL->DISK instead of SAVE-LAYER, and DISK->NL instead of LOAD-LAYER. —Ed.

read a data file, calculate the required scaling factors, and save these to disk. Finally, a general-purpose word to train a network is presented. It is customised to a particular application by assignments made to four deferred words. An example that uses these words is given.

Words to copy a network layer to and from disk

SAVE-LAYER
This word saves a neural

and works out the scaling factor to scale the real life input and output values to the range from -0.5 to +0.5, which suit the non-linear transform in use. After the scale factors have been set, the words SCALE-IN# and SCALE-OUT# scale an input or output number. The word UNSCALE-OUT# returns an output from internal representation to real life units. The scaling factors can be saved to disk and restored from disk with SAVE-SCALES and READ-SCALES, respectively. Each of these words must be immediately followed by the name of the file to use.

The generic training word

TEACH-NETWORK is the top generic training word. It expects the number of training passes to be on the stack on entry, but if the stack is empty it defaults to 1000 cases. It must be followed by the name of the data file to use. It does not establish the scale factors—these must have been just calculated, or a previously generated set must have been read from disk.

TEACH-NETWORK contains four deferred words, and these must be pointed to the routines for the specific task in hand. The deferred words, and their functions, are:

DO-INIT

This may do any initialization of disk, display, or anything else required.

FORWARD-WORD

This performs one evaluation pass of the network, updating the internal activa-

tion of each output. It expects the inputs, already scaled, on the stack on entry. Once a network is trained, this is the basic word for using it in recall mode.

TRAIN-WORD

Given a set of scaled outputs on the stack, this word must calculate the errors in the outputs and back-propagate these to the network inputs, updating the weights as it goes. It leaves nothing on the stack.

DISPLAY-INFO

This is a word to display any information about the state of the network that may be desired. It is called after each training example.

With these words, TEACH-NETWORK will train for the specified number of cases or until a key is pressed. Figure One shows the code for the words described above. *[See Errata on page 17; the Figure One referred to here was printed as Figure Eight in the last issue.—Ed.]*

Example

Figure Two shows an example that uses TEACH-NETWORK, and Figure Three provides a suitable data file. Once again, the exclusive-or relationship is used so that the file is short, but any other could be substituted. The more complicated the relationship to be learned, the more neurones will be needed. If too few are used, the network either will not stabilise or will learn only the general features of the relationship and fail to learn the detail. Of course, this ability to generalize may be of con-

Figure Three. A small sample data file (XOR.DAT).

0	0	0	\	input	input	output
1	0	1	\	input	input	output
0	1	1	\	input	input	output
1	1	0	\	input	input	output

siderable interest in some situations. The error display is very simple, just printing the error for the four examples per line; since there are four possible examples, only this provides a simple way to see how the network is behaving. Alternatively, a simple four-graph plotting routine would make trends easier to observe.

Conclusion

The words presented here extend those in part one. Together, they provide a toolkit for constructing non-linear feed-forward networks and for training them by back propagation. They demonstrate again the power of Forth to produce a special language for a task. Following the approach used here, words could simply be produced to implement other types of neural layers, such

as self-organising Kohonen layers. By standardising on passing data between layers on the stack, networks of arbitrary complexity can be readily constructed, trained, and used.

Tim Hendtlass has used Forth for years, and teaches it to about 100 students per year at the Swinburne Institute of Technology. He relates, "Roughly half the class are taking Computer Science as their co-major and, by the time they get to me, have one year of programming and several (nearly) working programs under their belts; they are sure they know it all. The other half are taking Medical Biophysics and generally are not sure what a computer is, are sure they don't like it, and have a fear that touching the keyboard will result in the machine taking over their minds.

"Despite this difference in background, within about one semester they are all controlling instruments in the laboratory using multi-tasking and hardware interrupts, all written in Forth. They like it, to their collective surprise. I would be delighted to hear from anyone else teaching Forth as a primary language of choice and as a vehicle to let students achieve some non-computing-related objective (scientific instrumentation systems, in my case).

"I have developed a series of experiments that I would be glad to share, and I would welcome hearing about others' experiences. Write to me in care of the Swinburne Institute of Technology, P.O. Box 218, Hawthorn 3122, Australia; or fax to 8 19 5454."

Figure Two. An example using TEACH-NETWORK (NNDEMO2.SEQ).

NNDEMO.SEQ code pertaining to Part One.

```

\ Four examples of simple artificial neural networks.   Tim January 1990
\ *****
comment:
These examples all use simple non-linear feedforward networks and are trained
by back propagation.  For simplicity, they use very simple inputs.  Examples
2 to 4 all learn to impliment the exclusive or relationship, which practically
would never be generated this way!  Needs BASICNN to have been loaded, the
line below will check and load this file if it is not already loaded.

MAKE YOUR SMALL COMPUTER THINK BIG

(We've been doing it since 1977 for IBM PC, XT, AT, PS2, and TRS-80 models 1, 3, 4 & 4P.)

FOR THE OFFICE — Simplify and speed your work with our outstanding word processing, database handlers, and general ledger software. They are easy to use, powerful, with executive-look print-outs, reasonable site license costs and comfortable, reliable support. Ralph K. Andrist, author/historian, says: "FORTHWRITE lets me concentrate on my manuscript, not the computer." Stewart Johnson, Boston Mailing Co., says: "We use DATAHANDLER-PLUS because it's the best we've seen."

MMSFORTH System Disk	from \$179.95
Modular pricing — Integrate with System Disk only what you need:	
FORTHWRITE - Wordprocessor	\$99.95
DATAHANDLER - Database	\$59.95
DATAHANDLER-PLUS - Database	\$99.95
FORTHCOM - for Communications	\$49.95
GENERAL LEDGER - Accounting System	\$250.00

MMSFORTH

MILLER MICROCOMPUTER SERVICES
61 Lake Shore Road, Natick, MA 01760
(508)553-9138, 9 am - 9 pm

FOR PROGRAMMERS — Build programs FASTER and SMALLER with our "Intelligen" MMSFORTH System and applications modules, plus the famous MMSFORTH continuing support. Most modules include source code. Farren MacIntyre, oceanographer, says: "Forth is the language that microcomputers were invented to fit."

SOFTWARE MANUFACTURERS — Efficient software tools save time and money. MMSFORTH's flexibility, compactness and speed have resulted in better products in less time for a wide range of software developers including Ashton-Tate, Ercalibur Technologies, Lindbergh Systems, Lockheed Missile and Space Division, and NASA-Douglas.

MMSFORTH V2.4 System Disk from \$179.95
Needs only 24K RAM compared to 100K for BASIC, C, Pascal and others. Convert your computer into a Forth virtual machine with sophisticated Forth editor and related tools. This can result in 4 to 10 times greater productivity.

Modular pricing — Integrate with System Disk only what you need:	
EXPERT-2 - Expert System Development	\$69.95
FORTHCOM - Flexible data transfer	\$49.95
UTILITIES - Graphics, 8087 support and other facilities.	

and a little more!

THIRTY-DAY FREE OFFER — Free MMSFORTH GAMES DISK worth \$39.95, with purchase of MMSFORTH System, CRYPTOQUOTE HELPER, OHELLO, BREAK-FORTH and others.

Call for free brochure, technical info or pricing details.

A message from the President of the Forth Interest Group

President's Letter

ORGANIZATION, ISSUES, ACTIONS,
AND EXPLANATIONS.

Organization

Business Group

Summary of recent business meeting minutes for July 21, 1991 (full minutes of the Business Group are avail-

able upon request):

Membership dues (correction): In the last *FD*, I stated that the dues for the new student membership were \$24 per year. That was one

of the figures suggested, however the correct figure that was approved by the business group was a student membership of \$18 per year.

ADC Reports: There are now 1511 FIG members to date. This is an increase from last year at this time. This turn-around has been a long time in coming, and I expect the upward trend to continue.

Board of Directors

The nomination process for the Board of Directors has taken place. According to the FIG by-laws, a nomi-

(Continued on page 26.)

Who would complain if Forth were required in their project?

Ada Multiprocessor Real-Time Kernel

Hoyt A. Stearns, Jr.
Phoenix, Arizona

A fully pre-emptive, priority driven, multiprocessor real-time kernel is required in certain applications (process control, in this case). After evaluating several schemes, I decided that the Ada rendezvous method is simple, straightforward, and elegant. Ada multitasking will work on any configuration of multiple processors that can communicate, or on a single processor. A single task can be localized to a particular processor, or can be distributed among many.

The listing is the kernel for a system with three processors. In the actual implementation, one of the three processors is of a completely different type, which is handled by having two code fields in each Forth word. All processors share the same memory.

Having a processor of a different type added some complications in the listing not normally necessary—such as the constant `WS` for word size—since the processors were of different addressability.

The kernel works fine on a single-processor system, in which case all references to semaphores may be removed.

Memory is allocated from the top down, starting

at the contents of variable `RAMPTR`. First the system variables are allocated, then task control blocks (TCB's), as tasks are registered to the system with `REGIS`. Each TCB has three link fields, one for each processor, so a task may be registered to be scheduled among one to three processors.

Although this kernel implements the Ada rendezvous system, the syntax is, of course, different.

The Ada selective-wait structure is invoked in this system with the word `SELECT` (`S bit_mask timeout_value -`

Ada :in message, or where to copy the data if it is an Ada :out message.

The sender parameter is the address of the caller's TCB, and is used as a parameter to the word `RELEASE`, which is equivalent to the Ada `END_SELECT` construct.

Ada entry calls are implemented here with the word `CALL` (`S msg...timeout_value entry_# TCB_addr - msg...status`) where `timeout_value` is how many clock ticks to wait for receipt of the message before returning with `#call_expired` status. The other parameters are which

**Ada's multitasking works
on multiple processors
that can communicate,
or on a single processor.**

sender `&msg entry_#`), where each 1 bit in `bit_mask` represents an Ada entry that is open (`ADA ACCEPT`) and the `timeout_value` is how long in clock ticks to wait for a message on one of the open entries (`ADA DELAY`). The `entry_#` return parameter is which entry the message came in on, or the total number of entries on this task if it times out. The `&msg` is where to get data if this is an

entry on which task to call. The message parameters must be explicitly dropped after the call, since `CALL` has no way of knowing how big the message is.

Other functions available are pure `DELAY` and `IXMIT`, which sends a message without stalling the caller (mainly used to send messages from interrupts). In Ada, interrupt messages are received by tasks just as if

Ada listing.

they were from another task.

Improper structuring of tasks in a system may easily result in deadlocks. The word DEDLOK may be invoked periodically to break any deadlocks by returning the parameter #BROKEN to one of the CALL's involved. This shouldn't be necessary in a properly programmed embedded system.

There should be a MASTER task—registered to only one of the processors in the system—which registers the rest of the tasks, then calls slave tasks on the other processors, which start up their own schedulers.

Interrupts were handled in the target system by revectoring NEXT in the variable NP (next pointer) on a particular processor to high-level code to post an IXMIT message, then revectoring NEXT back to normal. NEXT may also be vectored for tracing.

There is an ancillary task, SYSTAT, which takes a snapshot of the entire system and prints a report of task status, message queues, run-time statistics, etc.—but that is for another article.

(Code continues.)

(President, from page 23.)

nating committee consisting of two members of the Board of Directors (John Hall and Dennis Ruffer) was appointed. After a search for candidates, three were selected to fill the vacant positions. They are Mike Elola, current board member; Nick Solntseff, southern Ontario FIG Chapter; and Jack Woehr. Since there were insufficient write-in petitions (25) for any other candidate, an election by ballot by the membership is not required. A unanimous vote for the nominees will be cast by the Secretary at the annual meeting of the Board of Directors in November. These candidates will submit personal statements in the November-December issue of *Forth Dimensions*.

Issues, Actions and Explanations

Treasurer has prepared review of FIG financial situation. The treasurer has prepared, and the Board has approved, the financial statement presented in this *FD*. In explanation, April 30 is the end of FIG's fiscal year and the figures reflect those dates. The form is similar to a "Statement of Change in Financial Position" changed to reflect the year-ends for 1990 and 1991 with comparison. This form shows Assets and Liabilities, and the differences. Most categories are clear, with the exception of the "FD Dues Alloc. to future months *FD*" and "Financial Reserve." "FD Dues Alloc to future months *FD*" is money received by FIG, budgeted to complete a member's year of *Forth Dimensions* (this is the amount FIG is obligated to put aside to produce fu-

ture issues of *FD*). "Financial Reserve" is the difference between Assets and Liabilities, and indicates the state of FIG if all Assets were liquidated to pay all Liabilities. It is an indication of the health of FIG.

Complete financial reports are available in the FIG offices and are open for inspection.

Public relations. For the last several months, the focus of the Business Group has been on publicity for Forth and FIG. There are several lines of attack that we are preparing to take. In the past, our approach has been to try to encourage individual programmers to look at Forth and, when they do, to use FIG as a resource. We are shifting the emphasis of exposure toward what I call, for lack of a better term, the "mid-level manager"—the people who control the direction of projects, who have some control of a budget, and who want to get the most product for the money they control. The emphasis will be on the innovation that is going on in Forth, the fact that there are people ready and available to help with their projects, and the wealth of information that is already available. These are the exact people about whom I have heard the complaint, "If only these people understood what could really be done with Forth, my life would be a lot easier." These are the people that I have heard complain, "I would like to use Forth, but where am I going to find enough of the right people to produce and maintain my project?" Two specific types in this group, to give you a better feel of

what I mean by mid-level manager, are project leaders, at all levels of industry; and researchers in R&D organizations, whether universities or R&D divisions of larger companies.

How do we entice them?

The primary way will be with articles in all appropriate trade publications about the innovative ways that Forth is being used to solve current problems. Highlighted will be individuals or teams or applications or Forth vendors' products or standards or places where Forth already is used but the fact is generally unknown. The emphasis will be on innovative ideas and innovative people!

Second, by volume we let them know that they have always been surrounded by Forth and that the idea of using it is not novel—in fact, that it is required and that there have always been people near them who are willing to help.

Third, that FIG is one of their conduits for information about Forth, whether it is for literature, training, people, or direction toward vendor products. We will emphasize all the Forth resources available to make them and their projects successful.

How do we do all this? This is a multi-path attack, and one of the places it starts is with you!

1. If you will soon be writing a technical article about your project, you will see an article in the next *FD* about the style and approach that FIG would like you to add to your article. Horace Simmons has been compiling a list of the publications that will be the vehicles for this endeavor.

2. If you are on a project that is new and interesting, and you are interested in letting others know and can write about the technical parts, we will find a writer that can reshape it into an article that will complement the technical aspects with general-interest aspects of Forth and will help find an appropriate place to get it published.

3. As articles are published, we will coordinate Forth- and FIG-related advertisement to be placed in those issues along with the articles.

Why are we emphasizing mid-level managers? They are the people who specify or can direct the technical details of a project. They are the people who put together a project team. They are the people who would most likely pale at new innovation without justification. They are the people who make a project succeed or fail. They are the people we have failed to reach. Who of us would complain if Forth were required in your project?

I am always available for comments.

—John Hall

JDHALL on GENie

(Letters, from page 16.)

CREATE, CREATE DOES>, and, in some Forths, also VARIABLE, will need to be recoded. As of today, if you are using Forth and you want your application to be compatible with future hardware and system software, you have to refrain from using some very natural Forth mechanisms. This is all very un-Forth-like!

Forth could and should, if only some more people bothered, evolve on the Macintosh. There is no reason why the vast programming utilities of MPW, its many tools, its great multi-scrollbar editor, could not become available to the Forth environment. I myself am depending more and more on the MPW environment and, yet, it still lacks the one thing taken for granted in any Forth environment: interactivity—the kind you get by being able to compile small entities and immediately execute and debug them.

I think that if Forth has proved to be a disappointment on the Mac, one has only oneself to blame. With Forth's simple and open "architecture," the compiler is not the limit, the user is.

As an update to the report I sent, I would like to confirm that the discussions with IBM were successful, and they will be hosting our next London meeting. Incidentally, they have been most generous in supplying not only space in their South Bank Lecture Theatre, but also a buffet meal. Perhaps other FIG Chapters would be interested to know that there is some benefit to be made from approaching large corporations with regards to meetings. We are currently trying to encourage them to attend euroFORML.

The FANSI project is proceeding apace, and initial circuit diagrams have been drawn up for our planned processor board. We have actually settled on a 6309 processor, which is a CMOS 6809. This was chosen for its low cost and availability, and for the orthogonality of its instruction set and direct support for two stacks. It is possible that, in the future, we will produce a second board using a stack processor, very possibly the German device designed by Klaus Schleisiek-Kern, incidentally the organizer of this year's euroFORML.

Yours sincerely,
Gordon Charlton

I have been using Forth since 1978. Most of the professional work I have done has been embedded software in traffic monitoring equipment for an outfit called

Golden River. More recently, I wrote an implementation of Forth-83 for the Transputer. I started working on the Matching Birthdays problem as a result of Gil's blatant provocation in asserting it was a formidable calculation. My first attempt performed the entire calculation on the stack and ran to six screens of source code. My general thoughts about Forth are that it is a good thing.

*Big Number Arithmetic
and the Probability of
Matching Birthdays*

In the editorial of *Forthwrite* 56, Gil gave the formula for calculating the probability of finding at least one pair of matching birthdays in a group of n people as $(1 - P)$, where P is found by multiplying all the integers in the range $(366 - n)$ to 365 inclusive, then dividing by 365^n times.

To obtain four decimal places using integer arithmetic, we must multiply by 10,000 and subtract the result from 10,000. All the multiplication must be performed before the division, giving rise to very big intermediate values. It is only necessary to multiply and divide by single-length numbers, so the algorithms for "short multiplication" and "short division" are used; the product or quotient is written, cell-by-cell, back to the same memory locations that held the corresponding cells of the multiplicand or dividend.

It is interesting to compare the results of this program with those which Gil obtained using the Monte Carlo method. The big num-

One-Screen

Full-Screen Editor

Our company, M.A.S.S., operates as a bespoke software house working with a wide variety of projects, 90% of which are now Forth based.

Between jobs, I get involved in what can loosely be called R&D. This can range from developing software tools (tinkering with Forth), looking at ways to improve efficiency (making a case for the latest hardware), and exploring software techniques (playing games).

Seriously, though, we started to move over to Forth in about 1985, after studying the language (during R&D) and comparing it to the languages used at the time, i.e., BASIC, Pascal, and assembler. The benefits gained came slowly, at first, but then at an accelerating rate as experience was gained and the various "pennies dropped."

We tried several commercial versions of Forth, with varying levels of success, before developing homegrown versions. This gives us absolute control to customize as required. Forth makes you greedy!

One of the many benefits Forth gives us is the ability to very quickly produce prototypes. While our competitors are busy drawing up impressive-looking flowcharts and "tecspecs," we are demonstrating some sort of prototype to which the client

usually can relate. This has worked very well for us. (As a point of interest, we have had over 12,000 Forth applications distributed worldwide.)

Another R&D session looked long and hard at C. I obviously missed something. All that syntax!

Yet another period of R&D produced the one-page full-screen editor. We were working on text manipulation at the time, so I lifted some of the code and worked on minimizing it.

I would not have believed that any sort of screen editor would have fit into 1K of source code—"packed jumble" or not—especially as the editing facilities offered are quite respectable. The average words per definition worked out to fewer than six, and only an improvement to the word TYPE makes any significant improvement to performance.

I found the competition a worthwhile exercise and, indeed, have imposed the one-screen restriction on several pieces of code since. This approach forces a re-think and a re-work of just about every word used. Perhaps Gordon Charlton has unwittingly opened up a whole new programming technique? I cannot, however, recommend the regular use of the style used in my example! [See Figure Two on page 36.]

—Mike Lake

Conscientious Computing

Omni magazine's May 1991 issue contains a guide to energy-efficient behavior, something many technophiles appreciate as a kind of self-preservation. Among their suggestions related to office work: use machines with controls that keep them from running at full power during work lulls; save your laser printers for output that demands their quality output (they require ten times as much energy as other printers); use a fax *without* a

thermal print mechanism; use laptop computers, which are more efficient than desktop models; use smaller screens; use recycled paper; and carpool or, better yet (take my word for it), telecommute.

For quantity reprints of

the complete *Omni Energy Efficiency Guide*, write to *Omni Energy Guide*, 1965 Broadway, New York, NY 10023.

THINKING FORTH

A Language and Philosophy for
Solving Problems

BY LEO BRODIE

SEE FIG MAIL ORDER FORM IN THIS ISSUE!

ATTENTION FORTH AUTHORS!

AUTHOR RECOGNITION PROGRAM

TO RECOGNIZE AND REWARD AUTHORS OF FORTH-RELATED ARTICLES, THE FORTH INTEREST GROUP HAS ADOPTED THE AUTHOR RECOGNITION PROGRAM.

Articles

The author of any Forth-related article published in a periodical or in the proceedings of a non-Forth conference is awarded one year's membership in the Forth Interest Group, subject to these conditions:

- a. The membership awarded is for the membership year following the one during which the article was published.
- b. Only one membership per person is awarded in any year, regardless of the number of articles the person published in that year.
- c. The article's length must be one page or more in the magazine in which it appeared.
- d. The author must submit the printed article (photocopies are accepted) to the Forth Interest Group, including identification of the magazine and issue in which it appeared, within sixty days of publication. In return, the author will be sent a coupon good for the following year's membership.
- e. If the original article was published in a language other than English, the article must be accompanied by an English translation or summary.

Letters to the Editor

Letters to the editor are, in effect, short articles, and so deserve recognition. The author of a Forth-related letter to an editor published in any magazine except *Forth Dimensions* is awarded \$10 credit toward FIG membership dues, subject to these conditions:

- a. The credit applies only to membership dues for the membership year following the one in which the letter was published.
- b. The maximum award in any year to one person will not exceed the full cost of the FIG membership dues for the following year.
- c. The author must submit to the Forth Interest Group a photocopy of the printed letter, including identification of the magazine and issue in which it appeared, within sixty days of publication. A coupon worth \$10 toward the following year's membership will then be sent to the author.
- d. If the original letter was published in a language other than English, the letter must be accompanied by an English translation or summary.

(Letters, from page 34.)

FD XIII/1), I supplied words that would enter the PDE editor automatically if a load error occurred—(ERROR), (WHERE), etc. on screen 11. At the time, I thought these words crashproof. I spoke too soon. Since then, I've discovered a rather obscure bug that will crash the system like a fireworks display.

This happens when you first load Forth from the CP/M or DOS command line and decide to provide as an argument a filename for Forth to open. Should you misspell the filename or give one that does not exist, an open-file error occurs, the PDE editor is entered, and crash.

Yet the same open error done from the Forth command line results in the expected error message and no problems.

The trouble starts back when you take the pristine Kernel83 and add the extensions and assembler. As a kindness, the load screen ends by doing the SAVE-SYSTEM for you. Because of this, the variable BLK is saved as having a value of one, as this is the load screen number.

When you first load in Forth, I found that the boot routine is provided by START, which in turn calls DEFAULT. DEFAULT searches CP/M's DMA (on my computer) for a filename to open. Normally, this happens smoothly, and the sequence exits through QUIT. But in an open file error, it exits through ERROR. Unfortunately, nowhere is BLK reset to zero beforehand. Now (ERROR)

in my PDE uses a non-zero BLK as a flag that the error occurred during a load, so it enters the editor. This causes the system to crash.

However, in setting up the Forth command line, QUIT early on resets BLK to zero, so an error there displays the error message normally.

You can solve the problem at several levels.

1. Simplest is to redo the SAVE-SYSTEM from the Forth command line. This ensures that BLK is zero.

2. You can rewrite START to include 0 BLK ! before calling DEFAULT. It's easy to patch in, as BOOT is a deferred word. Then, future additions to the program using this load screen to save the system won't cause problems.

3. Ultimately, correcting DEFAULT to reset BLK and recompiling would guarantee that this gremlin won't return to haunt you.

Yours truly,
Walter J. Rottenkolber

Answer to a Dream

Dear Sir,
In answer to John G. Derrickson's letter requesting a low-cost, better Forth ("Dreaming That It's Forth," FD XIII/2), I would like to recommend Upper Deck Forth, available from Upper Deck Systems (P.O. Box 263342, Escondido, California 92026).

I have found it to be exceptionally fast and easy to use. It is a text-based system and incorporates such

\$ Contest Announcement \$

Deadline: September 16, 1991
See editorial in issue XIII/1 for details!

features as mouse control for the full-screen editor, direct access to DOS functions from the terminal input stream, full memory usage, disas-

during compilation, so determination of the exact location of the interrupt routine was made more difficult. This was solved by readjust-

I would not have believed that any sort of screen editor would have fit into 1K of source code.

sembler, assembler, and support for generating headerless, turnkey applications.

The only difficulty I encountered when using Upper Deck was while writing an assembler interrupt routine that required absolute addressing. The dynamic memory allocation readjusted segment and offset addresses

ing the code within the interrupt routine after compiling.

I highly recommend this MS-DOS Forth system.

Sincerely,
Glen F. Ingle

Best of GENie

In the February column I promised not to delay so long between recaps of guest conferences. Before making good on that promise, I want to call your attention to the improved appearance of the GENie Forth RoundTable. Topics and entire categories are much cleaner. The rat's nests of messages, many of which my ForthNet message ports created, are largely gone. All this can be attributed to our newest SysOp, Elliott Chapin. Elliott came on board knowing he would have to pick up after the likes of me, so he is either one heck of a good guy or a glutton for thankless jobs. I happen to believe the "nice guy" theory will stand the test of time.

Here, in his own words, is Elliott's introduction: "I was born in 1942 in New York City, just five days before my better known half-nephew Harry. A couple of years later, my father James Chapin, an established artist, moved the family out to rural northwest New Jersey. Now I have a family of my own in Toronto. I studied math at Princeton (starting my acquaintance with computers there) and Columbia in the 60s. Since then, I have found various kinds of work in the arts and education, but I also drive a taxi when necessary. I am enjoying the learning oppor-

tunities available on the GENie's Forth RoundTable, while doing "slash and stash" messagebase edits as the latest assistant SysOp." (Note: ELLIOTT.C is Elliott's e-mail address.)

Welcome to the funhouse, Elliott.

* * *

It is true that revisits with our guests in this column never capture the intimacy of the Real-Time Conference where you pose the question, usually sparked by another comment, but they do serve to remind attendees of poignant exchanges and to let non-participants know what they missed. Transcripts of the complete conferences are archived in the GENie Forth RoundTable's Software Library 1. Please make a note, as you scan this column, to download those you find of value, because the conferences as presented in this column are reduced to the guests' opening remarks.

Guest conferences reviewed here include Jef Raskin, "What Happened to the Cat?"; Alan Furman, "ACM SIGForth Update"; Bill Muench, "Embedded with eForth"; Guy Kelly, "Forth and Industry"; Dean Sanderson, "Addressing Management Concerns" (regarding use of Forth); Roy Martens and Glen Haydon, "MVP is Alive and, well..."; Charles Johnsen, "Mutable

Instruction Set Computers."

Jef Raskin, creator of the Mac and Canon Cat, asked "What happened to the Cat?" in reference to the marketing failure of the Canon Cat. This initial discussion rapidly gave way to a more thorough look at what the interface between computer and man should be—certainly an area, it can be safely argued, in which Jef Raskin is one of the ranking authorities, if not the authority. 10/17/90

Jef Raskin: I am pleased to be here, and I think that it might be best to just start with questions. When I see the directions the questions take, I can make more extended comments.

Cool CAT JAX: First I were a Programmer... Now I am a Project Engineer... Jef, how long do I have to wait before I start having Ideas? :-)

Jef Raskin: Thank you Mr. Cat. My real interest these days is in interfaces. For example, windows are dumb, icons wrong, and mouses a nuisance.

Dennis Ruffer: Sticking to that "heresy," let me ask how/why did you start the Mac project?

Jef Raskin: I can't stand the usual hand-to-mouse exist-

ence. The real question is why we have to bother with all those "features" when we are trying to get something done. I started the Mac project in 1979. I have learned something in the intervening decade. In those days I was (correctly, I think) inspired by the work at PARC. But one mustn't confuse "better" with "good." The Mac was better, but one can go a lot better.

WilBaden: Please tell us what you think happened to the CAT.

Jef Raskin: It was, I have been told, a victim of internecine warfare within Canon and a lack of marketing support. I am sure of the second hypothesis.

Gary Smith: There was excitement here after John Bumgarner was in conference with Steve Roberts about the possibility of a portable, personal Forth laptop then *bingo*/the CAT is on sale in Service Merchandise. That's a lot of smoke and mirrors. Any further comment?

Jef Raskin: They are, by the way, still available. A guy, David Wing, in San Diego has kept track of them. Canon did not know what it had, and tried to sell it through its electronic typewriter division. This was a mistake. Then they tried selling it for twice the design price. That was a mistake. We did make some prototype portables, I have one here and it works (and runs Forth), but our Vulture Capitalists had lost their stomachs (and minds).

Dr. Alan Furman, independent software and electronics consultant, presented an

update on a sister organization, SIGForth ACM. As a principle of this group's genesis, Dr. Furman was more than qualified to do so.

11/15/90

I should begin by acknowledging the tremendous contribution of George Shaw, who has been the driving force in SIGForth from the beginning. My main role was as a crusader, in late 1988, for some kind of organization that would specialize in professional issues and the commercialization of Forth. FIG's constituency is a mixture of professionals and hobbyists. And many of those professionals didn't care who admired Forth; they were in a position of having discretion over programming language. Whenever you have a group of people together, you have to stick to things that they are all interested in at the same time, which in FIG's case is Forth technology and sharing of ideas.

I will close with some exciting news. The Forth community in Leningrad would like to put on a conference either Fall 1991 or Spring 1992, which will be run in cooperation with SIGForth.

Bill Muench, president of Ontologic and coauthor of eForth, discussed eForth, the .asm Forth kernel for the 90s.

12/13/90

eFORTH is derived from my commercial version bFORTH. Both are ANS Forth subsets. I designed eFORTH for ease of implementing new systems, to easily fit in 8K bytes, to have a minimum of machine code and some debugging tools. My debug tools are TX!, the transmit primitive, .S,DUMP, and WORDS. I use a simple metacompiler rather than MASM, which

means I first write an assembler. That is how I get to know the processor.

After the new system is running, I optimize it, first loading the assembler, then new code words. When working, they are added to the kernel, repeat 'til done.

I use my host file server, bHOST, to upload source text files to the target system. MASM was chosen by Dr. C.H. Ting as a vehicle to communicate eFORTH. It is commonly available and on a widely used platform, the PC. But any assembler will do. Possible alternatives are spreadsheets or word processors with macros.

Guy Kelly expanded on his November 1990 FORML theme, "Forth in Industry." Guy has a vast array of Forth-driven industrial projects to his credit to support his views that Forth is an excellent platform for such endeavors.

1/17/91

Experiences as a Forth producer, user, and teacher convince me that it's almost impossible to get a professional programmer to use Forth and almost impossible to discourage a professional engineer from using Forth.

Now that Laxen, Perry, and Zimmer have handled the "high end" and Dr. Ting is attacking the "low end," how about the "Forth as a hardware development tool" area?

Dean Sanderson, software engineer with FORTH Inc., discussed "Addressing Management Concerns over use of Forth as an Applications Platform."

2/21/91

Because of the power that Forth has given us (to keep projects small and quick), we have been able to avoid learning what others have had to about software devel-

opment. Those who have grown up with Forth do management by intuition. We have trouble communicating with those who've been successful using Fortran, C, or assembler. It's as if we speak different languages. As projects escalate, we find we have not killed the dragon, only maimed him. As we ready for battle, we find our pride has left us with few new weapons.

For Forth to survive as a respected language, it must prove its adaptability and change enough to support the concerns of management. These include: Integration, Maintenance, Documentation, Declining cost, Q.A., Configuration, and Scheduling.

Though we've started late, we can survive by capitalizing on what others have learned.

This conference's invited co-guests were Roy Martens, president of Mountain View Press, with Glen Haydon, author of MVP Forth. Glen discussed the fate of MVP in the 1990s market.

3/4/91
Thank you for inviting Mountain View Press. We are alive, but changes are in store. Roy has sold his home and is moving to San Francisco. He is taking an apartment April 1. We have agreed for me to take over Mountain View Press. As some of you know, Phil Koopman, has taken a new job which requires him to divest himself of WISC Technologies. Epsilon Lyra is my company. I am bringing WISC Technologies in as a division. Roy and I agree to doing the same with Mountain View Press.

I plan on carrying the public-domain versions of Forth which I included in my new edition of *All About Forth*: fig-FORTH, MVP-

FORTH, F83, and F-PC. I will also carry available documentation.

We will also carry professional implementations from vendors who will make appropriate distributor's agreements. For the present, we will keep the same mailing address and phone numbers. We look forward to continuing our support of Forth users.

Charles Johnsen, President of MISC, Inc. (Mutable Instruction Set Computer, formerly Minimum Instruction Set Computer) was our invited guest. Charles was joined by Dr. David Fox, MISC's Software Engineer as the two discussed this new silicon engine.

4/18/91

Thanks for the welcome. I wanted to speak about the Silicon Palimpsest this evening. That is the processor without a fixed instruction set. MISC originally stood for Minimum Instruction Set Computer. It was a tiny company (and still is), set up to create a Forth stack engine.

We wanted to do something different from Novix. We wanted a processor for embedded control, not desktop computing. That guided our efforts and our business. Today we have changed our name to Mutable Instruction Set Computer, Inc., because we have an even better idea. By using FPGA (field-programmable gate arrays), we believe we can create a processor with a mutable instruction set. The advantage of a mutable instruction set is that custom instructions can be designed for improved performance.

In Recognition

Recognition is offered annually to a person who has made an outstanding contribution in support of Forth and the Forth Interest Group. The individual is nominated and selected by previous recipients of the "FIGGY." Each receives an engraved award, and is named on a plaque in the administrative offices.

FORML CONFERENCE

*The original technical conference
for professional Forth programmers, managers, vendors, and users.*

Following Thanksgiving, November 29–December 1, 1991

Asilomar Conference Center
Monterey Peninsula overlooking the Pacific Ocean
Pacific Grove, California U.S.A.

Theme: Simulation and Robotics

Papers are invited that address relevant issues in the development and use of Forth in simulation and robotics. Virtual realities, robotics, and graphical user interfaces are topics of particular interest. Papers about other Forth topics are also welcome.

Attendees are invited to enter a robot in a robotics contest where the robot solves a puzzle.

Mail abstract(s) of approximately 100 words by September 1, 1991 to **FORML Conference, Forth Interest Group, P.O. Box 8231, San Jose, CA 95155.**

Completed papers are due November 1, 1991.

Conference Registration

Registration fee for conference attendees includes conference registration, coffee breaks, and note-book of papers submitted, and for everyone rooms Friday and Saturday, all meals including lunch Friday through lunch Sunday, wine and cheese parties Friday and Saturday nights, and use of Asilomar facilities.

Conference attendee in double room—\$350 • Non-conference guest in same room—\$200 • Children under 17 years old in same room—\$140 • Infants under 2 years old in same room—free • Conference attendee in single room—\$450
Forth Interest Group members and their guests eligible for ten percent discount on registration fees.

Register by calling the Forth Interest Group business office at (408) 277-0668 or writing to: **FORML Conference, Forth Interest Group, P.O. Box 8231, San Jose, CA 95155.**
