

## CHAPTER 24. 8086 ASSEMBLER

The source code of the assembler is in CPU8086.BLK, screens 3 to 17, and KERNEL86.BLK, screen 80.

The assembler in FORTH allows the user to define words which will be executed at the raw machine speed and make use of all the resource in the host computer hardware system. It is often used to optimize a system or application program by recoding the critical or most often executed words to improve the performance of the program. A high level word can be substituted by a machine code word if the interface to the system, most notably the stack effect is kept the same.

The assembler is invoked by the defining word CODE which creates a header in the dictionary and makes the code field point to the parameter field. Machine instructions can then be compiled into the parameter field by a set of machine code words with mnemonic names similar to those used in regular assembler of the host processor. These machine code words are executed by the text interpreter and the net effect is to add new machine instructions to the parameter field so that when the new CODE word is executed, these machine instructions are executed in sequence. A CODE word must be terminated by the inner interpreter NEXT or its derivative to return control to the calling word, and the code ending word END-CODE or C;, which makes the new word available for execution or compilation.

### 24.1. ASSEMBLY TOOLS

A set of tool words is needed to assemble a machine code word in its most primitive form. If the user knows the host processor well enough, he can hand code a routine and generate a Forth CODE word without using the assembler.

VARIABLE AVOC		A variable holding the old context vocabulary during assembling.
: CODE	( --- )	The defining word that starts the assembling process to build a machine code word.
CREATE		Create the name field, link field, and code field for a new entry in the dictionary.
HIDE		Smudge the header to hide the new word before it is completed.
HERE DUP 2- !		Store the pfa into code field. This is required for indirectly threaded code.
CONTEXT @ AVOC !		Save the old context vocabulary.
ASSEMBLER		Use the ASSEMBLER as the context vocabulary to assemble machine code.
;		
: LABEL	( --- )	Mark the start of a subroutine. Return its address when the label is invoked.
CREATE		Create the header.

ASSEMBLER

Select context vocabulary.

;

232 CONSTANT DOES-OP            Op-code for CALL instruction used in DOES>.  
 3 CONSTANT DOES-SIZE            A CALL instruction consumes 3 bytes.

```
: DOES?      ( ip --- ip+3 f )    Return a true flag with the IP moved over the CALL
                                   instruction.
      DUP DOES-SIZE +              IP incremented by DOES-SIZE.
      SWAP C@                      Code at IP.
      DOES-OP =                    True if the opcode is CALL.
      ;
```

ASSEMBLER DEFINITIONS            All the assembler tool words are to be collected in this vocabulary.

```
: END-CODE      ( --- )           Terminate a code definition, make it available and also
                                   restore context vocabulary.
      AVOC @ CONTEXT !            Restore the old context vocabulary.
      REVEAL                      Unsmudge the header, making the word available to the text
                                   interpreter.
      ;
```

```
: C;            ( --- )           Synonym for END-CODE.
      END-CODE
      ;
```

The following set of deferred words are used in assembling machine instructions or constructing structures in the code definitions. They are defined as deferred words so that they can be shared by the assembler and the meta-compiler.

DEFER C,            ( byte --- )    Assemble a machine code byte to the dictionary.

FORTH ' C, ASSEMBLER IS C,        Vector it to the C, in FORTH vocabulary.

DEFER ,            ( n --- )        Assemble a cell to the dictionary.

FORTH ' , ASSEMBLER IS ,          Vector to the , (comma) in FORTH vocabulary.

C, and , are the primitive words used in the Forth assembler. Using them one can even generate code definitions without using an assembler. However, the machine code and operands have to be hand coded and stored into the dictionary by , and C, .

```
DEFER HERE      ( --- addr )        Return a pointer to the top of dictionary, the address of the
                                   next code to be assembled.
```

FORTH ' HERE ASSEMBLER IS HERE    Allow us to assembler code anywhere in memory.

DEFER ?>MARK                      Set up forward branch with error checking.

DEFER ?>RESOLVE                  Resolve a forward branch with error checking.

DEFER ?<MARK                      Set up a backward branch with error checking.

DEFER ?<RESOLVE

Resolve a backward branch with error checking.

## 24.2. 8086 REGISTER DEFINITIONS

Registers are used as operands, which are inserted into the register field in a machine instruction. They are thus defined as constants. The register constants are defined in the following format to facilitate the building of machine instructions which uses the corresponding register, as shown in Fig. 24.1. The lower byte may become a byte instruction or the second instruction byte to specify addressing mode. The upper byte with the mode field is used only during assembly.

OCTAL	8086 codes are best represented in octal due to the 3 bit fields.
: REG ( mode reg# --- )	Use the addressing mode and the register number to generate the proper register field to be defined as register constants.
11 * SWAP	Fill both reg and r/m fields.
1000 * OR	The addressing mode field.
CONSTANT	Defined as a constant to be inserted into register accessing code.
;	
: REGS ( n mode --- )	Define a set of register words which differ only in the register number.
SWAP 0 DO	Scan through n registers.
DUP I REG	Define each register as a constant.
LOOP DROP	Discard mode.
;	

Using the powerful REGS, we can define all the registers with all possible addressing modes as distinct Forth words returning the appropriate register constants to be used by machine code assembler words to construct machine instructions.

10 0 REGS	Define operands addressing only bytes in the registers.
AL CL DL BL AH CH DH BH	

10 1 REGS	Define operands addressing word registers.
AX CX DX BX SP BP SI DI	

10 2 REGS	Define indexed addressing operands.
[BX+SI] [BX+DI] [BP+SI] [BP+DI] [SI] [DI] [BP] [BX]	

4 2 REGS	Duplicated definitions.
[SI+BX] [DI+BX] [SI+BP] [DI+BP]	

4 3 REGS	Segment register addressing operands.
ES CS SS DS	

3 4 REGS	Immediate addressing operands.
# #) S#)	

Four registers are of special interests to the Forth system because they are used as registers in the virtual Forth machine. They are assigned generic names more appropriate in the manipulation of the Forth machine:

BP	CONSTANT	RP	The return stack pointer.
[BP]	CONSTANT	[RP]	Indirect addressing mode.
SI	CONSTANT	IP	The interpretive pointer.
[SI]	CONSTANT	[IP]	
BX	CONSTANT	W	The current word pointer.
[BX]	CONSTANT	[W]	

The data stack pointer uses the SP register which already has the correct name; therefore, it does not need a new name.

**Figure 24.1 Register addressing mode constant.**

#### Addressing Mode Byte

3	BL	BX	[BP+DI]	DS	segment
4	AH	SP	[SI]		
5	CH	BP	[DI]		
6	DH	SI	[BP]		
7	BH	DI	[BX]		

### 24.3. ADDRESSING MODE OPERATORS

```
: MD          ( mode --- )  Define words which will test various addressing modes.
    CREATE      Make header.
    1000 *,      Compile a template of addressing mode.
    DOES>       ( mode-field --- f )
    @           Get the template.
    SWAP 7000 AND Mask over the mode field.
    = 0<>       Return true if the mode matches.
    ;
```

```
0 MD R8?      ( operand --- f )  Is it in byte register mode?
1 MD R16?     ( operand --- f )  Is it in word register mode?
2 MD MEM?     ( operand --- f )  Is it in memory addressing mode?
3 MD SEG?     ( operand --- f )  Is it in segment addressing mode?
4 MD #?       ( operand --- f )  Is it in immediate addressing mode?
```

```
: REG?( operand --- f )      Test for either byte or word addressing mode.
    7000 AND                 Mask the mode field.
    2000 <                   Byte or cell.
    < 0<>                    Return the flag.
    ;
```

```
: BIG?        ( n --- f )      Test the size of address offset. Return true if n>255. ABS
    Absolute offset.
    -200 AND      Examine upper byte.
    0<>           True if not zero.
    ;
```

```
: RLOW        ( n1 --- n2 )    Retain only the low r/m field.
    7 AND;
```

```
: RMID        ( n1 --- n2 )    Retain only the middle register field.
    70 AND ;
```

VARIABLE SIZE                      A flag. True for 16 bit and false for 8 bit number.

```
: BYTE        ( --- )          Reset SIZE to indicate byte operations.
    SIZE OFF ;
```

```
: OP,         ( n opcode --- ) OR the operand and the opcode and assemble the machine
                                code.
    OR C, ;
```

```
: W,          ( opcode operand --- ) Assemble opcode with the W field set if operand
                                indicates a word register.
    R16? 1 AND      Set W field according to word mode.
    OP,             Assemble.
```

```

;
: SIZE,      ( opcode --- ) Assemble the opcode with W field determined by SIZE.  SIZE  @  1
AND          Set W field using SIZE.
OP,          Assemble.
;
```

```

: ,/C,          ( n f --- )    Assemble a cell if f is true. Otherwise assemble a byte.    IF      ,
                                f is true. Assemble a cell.
                                f is false. Assemble a byte.
    ELSE C,
    THEN ;

: RR, ( operand1 operand2 --- )    Assemble a register to register instruction.
    RMID                          Operand1 to r/m field.
    SWAP RLOW                      Operand2 to reg field.
    OR                             Register to register operand.
    300                            Register to register mode.
    OP,                            Assemble the reg-reg second instruction byte for
                                addressing.
;

VARIABLE LOGICAL                  True while assembling logical instructions.

: B/L?          ( n --- f )      BIG? of LOGICAL.
    BIG? LOGICAL @ OR
;

: MEM,          ( disp mr rmid --- )    Assemble a memory reference instruction. It takes a
                                displacement, and memory/ register, and a register as
                                arguments and encode them into an instruction.
    OVER #) =                    Is it in immediate indirect mode?
    IF                            Yes.
        RMID 6 OP,               Assemble immediate indirect instruction.
        DROP                     No need of mr now.
        ,                         Assemble disp, which is the immediate value.
    ELSE                          Not immediate indirect.
        RMID OVER RLOW OR        OR together the registers.
        -ROT                     Save it.
        [BP] =                   mr=[BP]?
        OVER 0= AND              AND disp=0?
        IF
            SWAP                  Get the register field to top.
            100 OP,               Byte displacement mode instruction. Mode 1.
            C,                     With the byte displacement.

## 24.4. DEFINING WORDS TO GENERATE OPCODES

8086 is a rather complicated microprocessor. It was designed to be 8080 downward compatible so that it must be able to execute all the 8080 instructions. With lots of 16 bit machine instructions and operators for the extra registers and different mode of operation, the instruction set becomes very involved. Consequently, the assembler also becomes complicated in order to take care of these diverse types of instructions. There are 14 identifiable classes of instructions in 8086. A defining word is used to generate opcodes for each class of instructions. .new .56 Fig. 24.2. 8086 instruction types.

THEN

```

THEN ;

## 24.6. STRUCTURES IN CODE DEFINITIONS

Structures similar to those in the regular colon definitions can also be assembled in code definitions. However, the structures in code definitions are constructed using the branching and looping machine instructions. The test condition for branching are not a flag on top of the data stack but the condition flags kept in the CPU status register.

Forward and backward branching are constructed using some words similar to the MARK and RESOLVE words in the colon definition.

```
: A?>MARK      ( --- f addr )  Set up a forward branch in code definition.
    TRUE        Leave a flag on stack for error checking.
    HERE        Address to branch from.
    0 C,        A dummy byte later to be resolved to a branching offset.
    ;

: A?>RESOLVE    ( f addr --- )  Resolve a forward branching.
    HERE OVER 1+ - Calculate the branching offset.
    SWAP C!      Store it after the branch instruction.
    ?CONDITION   Abort if the flag is not true.
    ;

: A?<MARK      ( --- f addr )  Set up a backward branch in code definition.
    TRUE        Set the flag.
    HERE        Leave current address on stack.
    ;

: A?<RESOLVE    ( f addr --- )  Resolve a backward branch.
    HERE 1+ -    Backward branch offset.
    C,           Assemble the offset. Complete the branching instruction.  ?
    CONDITION    Abort if flag is not true.
    ;
```

The branching instructions are vectored through the words >MARK, >RESOLVE, <MARK, and <RESOLVE. The execution routines vectored by these words can now be resolved by pointing them to the above structure words just defined in the assembler.

```
' A?>MARK ASSEMBLER IS ?>MARK
' A?>RESOLVE ASSEMBLER IS ?>RESOLVE
' A?<MARK ASSEMBLER IS ?<MARK
' A?<RESOLVE ASSEMBLER IS ?<RESOLVE
```

Conditionals in the assembler are machine codes to be assembled by the structure commands like IF, UNTIL, and WHILE. The conditionals are defined as constants to be assembled:

```
HEX
75 CONSTANT 0=   74 CONSTANT 0<>   79 CONSTANT 0<   78 CONSTANT 0>=
```

7D CONSTANT <	7C CONSTANT >=	7F CONSTANT <=	7E CONSTANT >
73 CONSTANT U<	72 CONSTANT U>=	77 CONSTANT U<=	78 CONSTANT U>
71 CONSTANT OV			
DECIMAL			

: IF     ( opcode --- f addr )	Assemble a conditional branch instruction to start a forward branch.
C,	Assemble conditional opcode.
?>MARK	Set up forward branch.
;	
: THEN       ( f addr --- )	Close a conditional branch.
?>RESOLVE ;	
: ELSE( f1 addr1 --- f2 addr2 )	Resolve forward branch for IF and set up another forward branch to THEN.
0EB	Unconditional branch opcode.
IF	Assemble it here.
2SWAP THEN	Resolve forward branch from IF.
;	
: BEGIN       ( --- f addr )	Set up a backward branch.
?<MARK     ;	
: UNTIL       ( f addr opcode --- )	Resolve the backward branch to BEGIN.
C,	Assemble the conditional opcode.
?<RESOLVE	Resolve the branch offset.
;	
: AGAIN       ( f addr opcode --- )	Resolve the backward branch with an unconditional branch instruction.
0EB	Unconditional branch.
UNTIL	Let UNTIL do the resolving and assembling.
;	
: WHILE       ( --- f addr )	Forward branch.
IF     ;	
: REPEAT       ( f1 addr1 f2 addr2 --- )	Branch back unconditionally.
2SWAP	Get the BEGIN location.
AGAIN	Assemble unconditional branch to BEGIN.
THEN	Resolve WHILE clause.
;	
: DO           ( n --- addr )	Set up an assembler do-loop.
# CX MOV	Assemble an instruction setting up the loop counter.
HERE	Leave address for branch instructions.
;	
: NEXT       ( --- )	The inner interpreter.
>NEXT #) JMP	Assemble an indirect jump.
;
